mod_tcl : TCL inside Apache
Olly Stephens

mod_tcl is an apache httpd module that allows TCL code to be
executed inside the web server during any of its phases whilst
handling requests. This tight integration makes possible many
things over and above simple page generation. Over the last
year I have been making some significant improvements to the
module, building upon the excellent work of the original 1.0
author and will soon be releasing a 2.0 alpha version.

This paper will start by discussing how apache serves requests
and how mod_tcl integrates into its pipeline. It will follow
this with examples demonstrating some of the more interesting
things you can do with this infrastructure; authentication
handling, URL rewriting, output filtering, dynamic logging.
Finally it will discuss the current state of the mod_tcl
codebase and future directions.
